

AlgoTradingMac - Current Component Architecture

Single Order Pipeline (UI + Strategy) and Safety Gates

Runtime Lifecycle and Control Plane

Startup -> Runtime -> Recovery

- 1) Build config + read Keychain credentials for selected env
- 2) Startup reconciliation: fetch account, positions, open orders
- 3) Connect trade_updates (auth + subscribe), then market data (multiplex)
- 4) Project stream events into Store snapshots consumed by UI/strategies
- 5) On disconnect/error: exponential backoff + reconnect + resubscribe
- 6) Debounced REST repairs: positions on fill, open-orders on lifecycle events
- 7) Proposal approval gate controls paper runs and strategy starts
- 8) IPC server starts on loopback with session token for alpaca_agentctl
- 9) On stop: cancel refreshers, stop streams, stop IPC cleanly

Principle: streams are authoritative for state transitions; REST is initialization + bounded repair only.
